Problem

| | |
|---|---|
| The Problem | Current emergency reporting and disaster response systems lack real-time data synchronization, leading to data inconsistency, duplicated records, and noise. Consequently, this hinders accurate and timely triage for critically vulnerable victims, preventing mission dispatches from reaching field rescue teams promptly. |
| Who is Affected | This issue impacts stakeholders across the entire response chain—from Incident Command Centers lacking operational visibility and Field Rescuers overburdened by fragmented workflows, to High-Risk Vulnerable Victims who rely on specialized medical equipment, such as bedridden patients requiring oxygen support or hemodialysis patients. |
| Impact & Urgency | Delays caused by manual coordination result in the loss of the critical "Golden Hour" needed to save lives. Furthermore, it causes severe misallocation of rescue capacity by deploying specialized assets—such as flat-bottom boats or portable power stations—to the wrong locations or to cases that do not match the actual urgency level. |

GATE 1 — REACHABLE USERS

1. Charatsap Khunnirong (General Consumer)
    - How you reach them Google Forms survey respondent with follow-up questions via Email ( jonatanazeiei@gmail.com )
    - When: September 9, 2026 (19:55:59)
2. Navin Sinthupum (General Consumer)
    - How you reach them : Google Forms survey respondent with follow-up questions via Email ( monster95.127@gmail.com )
    - When: September 9, 2026 (19:58:38)
3. Jirapong raima (General Consumer)
    - How you reach them : Google Forms survey respondent with follow-up questions via Email ( jirapong.rai@siam.edu )
    - When: September 9, 2026 (20:26:20)
4. Sayan (General Consumer)
    - How you reach them : Google Forms survey respondent with follow-up questions via Email ( sayankit1112@gmail.com)
    - When: September 9, 2026 (21:14:48)
5. Kasira (General Consumer)
    - How you reach them : Google Forms survey respondent with follow-up questions via Email( ninasayhi1288@gmail.com)
    - When: September 9, 2026 (21:56:13)

Gate 2 – MVP SHAPE

| | | |
|---|---|---|
| FR 1 | Victim Request Logging | Victims can log distress requests via the mobile app. |
| FR 2 | Data Synchronization | Offline request capture with sync when online. |
| FR 3 | Rescue Coordinator Live Map | Coordinators view all requests on a real time map. |
| FR 4 | Priority Scoring (Rule based) | Rule based scoring to quickly prioritize requests. |
| FR 5 | Communication & Contact | Coordinators can contact victims directly. |
| | -FR 3 and FR 5 carry a real rule or decision.<br>-FR 3 has to persist between sessions | |

Gate 3 – ACCESS

This data was self-provided by the user with explicit consent to be shared with responders in compliance with PDPA regulations.

PROCESS & TEAM

We selected the Agile SDLC for its flexibility to handle evolving requirements and support continuous future development.

1. The problem
    - During disaster emergencies, field rescue teams and coordinators face severe operational delays and duplicated efforts because fragmented reporting systems lack real-time data synchronization.
2. Root cause (from 5 Whys)
    2.1 Why is disaster response slow and duplicated?
    -Because rescue coordinators and field teams don't have a single source of truth for incoming distress calls.
    2.2 Why don't they have a single source of truth?
    -Because distress requests come from fragmented channels (phone calls, social media posts, LINE groups) and are manually recorded.Why are they relying on manual, fragmented reporting?
    -Because existing reporting tools fail when network connectivity drops, forcing people to use whatever basic communication works at the moment.
    2.3 Why does this break the whole operation?
    -Because when connectivity returns or teams move, no system automatically reconciles, syncs, and dedupes the offline/online data with accurate GPS locations.
    2.5 Why is this critical during a crisis?
    -Responders waste precious "Golden Hour" time verifying whether a request is already handled or if the victim is still trapped.

3. How do people solve it today, and what's bad about it?

- It doesn't exist,People are forced to stitch together general consumer apps.This results in data chaos, wasted rescue capacity, and preventable casualties.

4. Who has it + roughly how many (TAM)

- Target Audience: Residents in recurring disaster-prone areas (Demand) and local rescue teams/municipalities (Supply/B2B/B2G).
- Survey Validation: Out of 176 respondents, 92.6% stated they would download and use the app during disasters.

5. How often (frequency)

- For Citizens (End-users): Low frequency, high criticality $\approx 2\text{–}4$ times/year during peak monsoon and flash flood seasons.
- For Rescuers & Coordinators: $\approx 1\text{–}2$ times/week year-round for disaster preparedness drills, vulnerable group mapping (bedridden/elderly), and sensor monitoring.

6.Where do AI/software beat a human (can't/too slow)?

- Pre-emptive Snapshot Before Network Blackout (Human impossible): The app monitors battery drop and signal degradation to trigger an automated last-gasp push of GPS and status before the network drops completely—something humans cannot execute once offline.
- Instant Spatial Triage (Human too slow): The software automatically aggregates and clusters distress signals onto a live rescue map in milliseconds. Humans take hours manually scrolling through unorganized LINE chats and Facebook posts, leading to delayed rescues.

7.Remove “the app” — is it still solvable? (test whether software is truly needed)

-No.

8. Where do you find your first 3 real users (before Week 4)?

- Direct follow-up with engaged survey respondents who provided their emails for initial UI/UX testing and feature feedback.
